

Organic evolution considered

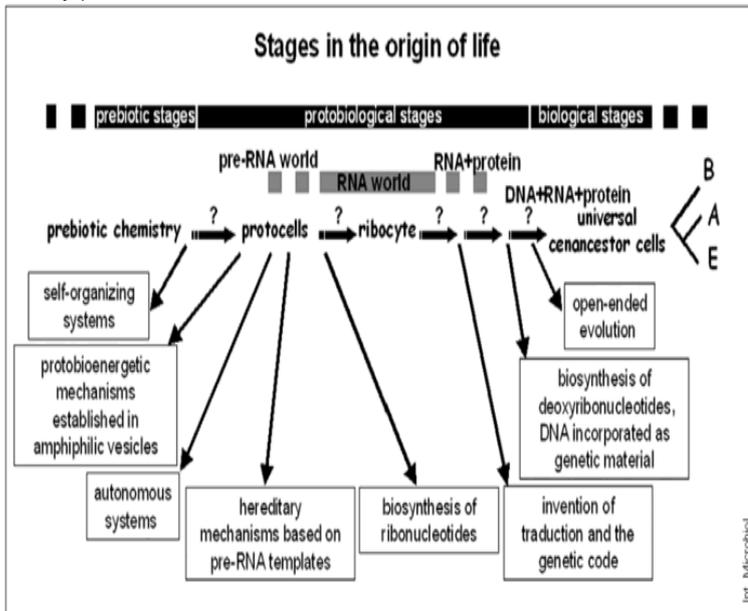

Fig. 3. A more detailed scheme of a hypothetical transition from prebiotic chemistry to cells. Protobiological stages comprise the origin of autonomous systems (protocells without genome), one-polymer protocells (including ribocytetes [42], i.e. protocells based only in RNA) and the early phases of a two-polymer (RNA and protein) world. True biological stages started with DNA-RNA-protein cells and their open-ended evolutionary capacities, i.e. the origin of life [34]. Arrows with question marks indicate unknown processes. The scheme does not imply a temporal scale, e.g. the transition from early DNA-RNA-protein cells to the universal ancestor might have been more prolonged in time. B: Bacteria domain, A: Archaea domain, E: Eucarya domain.
